

Colour Correction

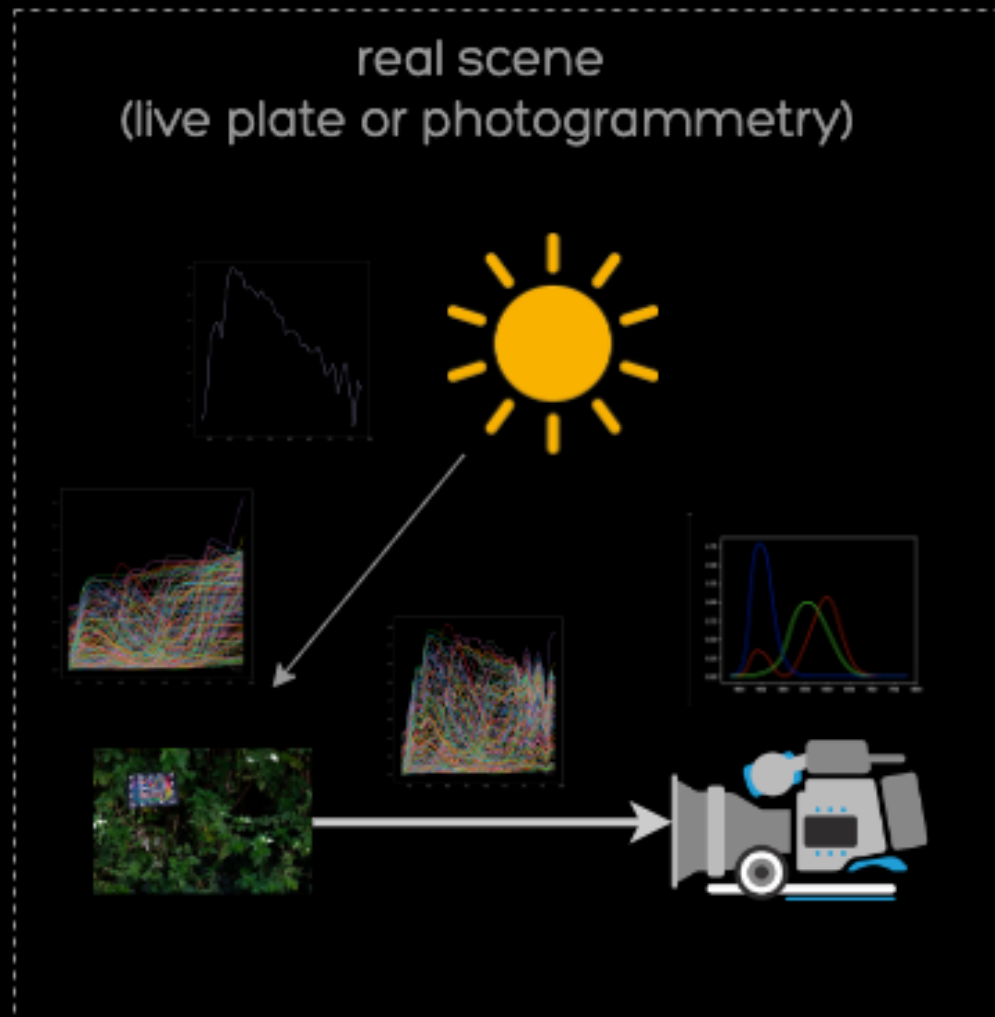

Foreground and Background

in Virtual Production

Calibration

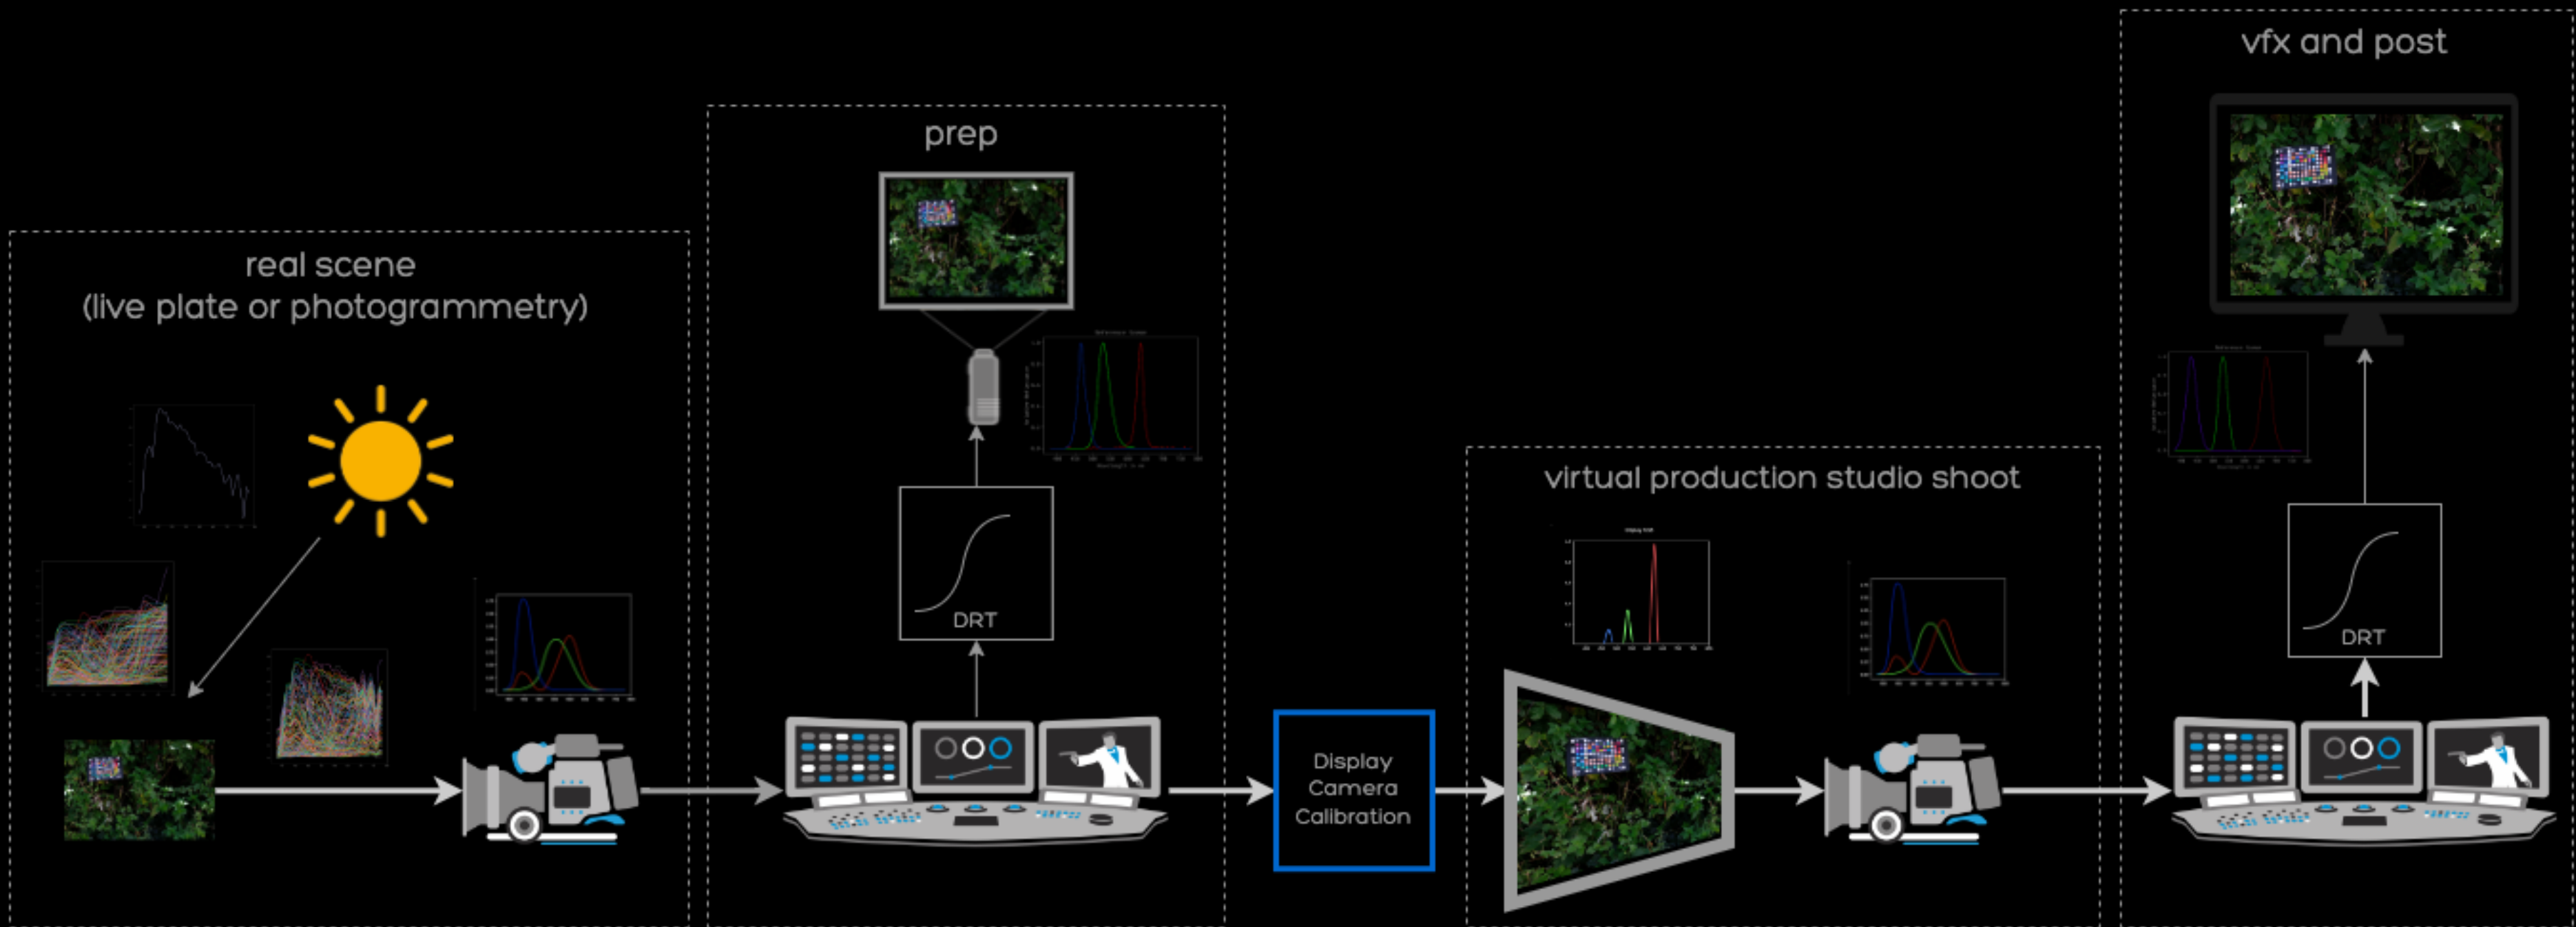

Calibration

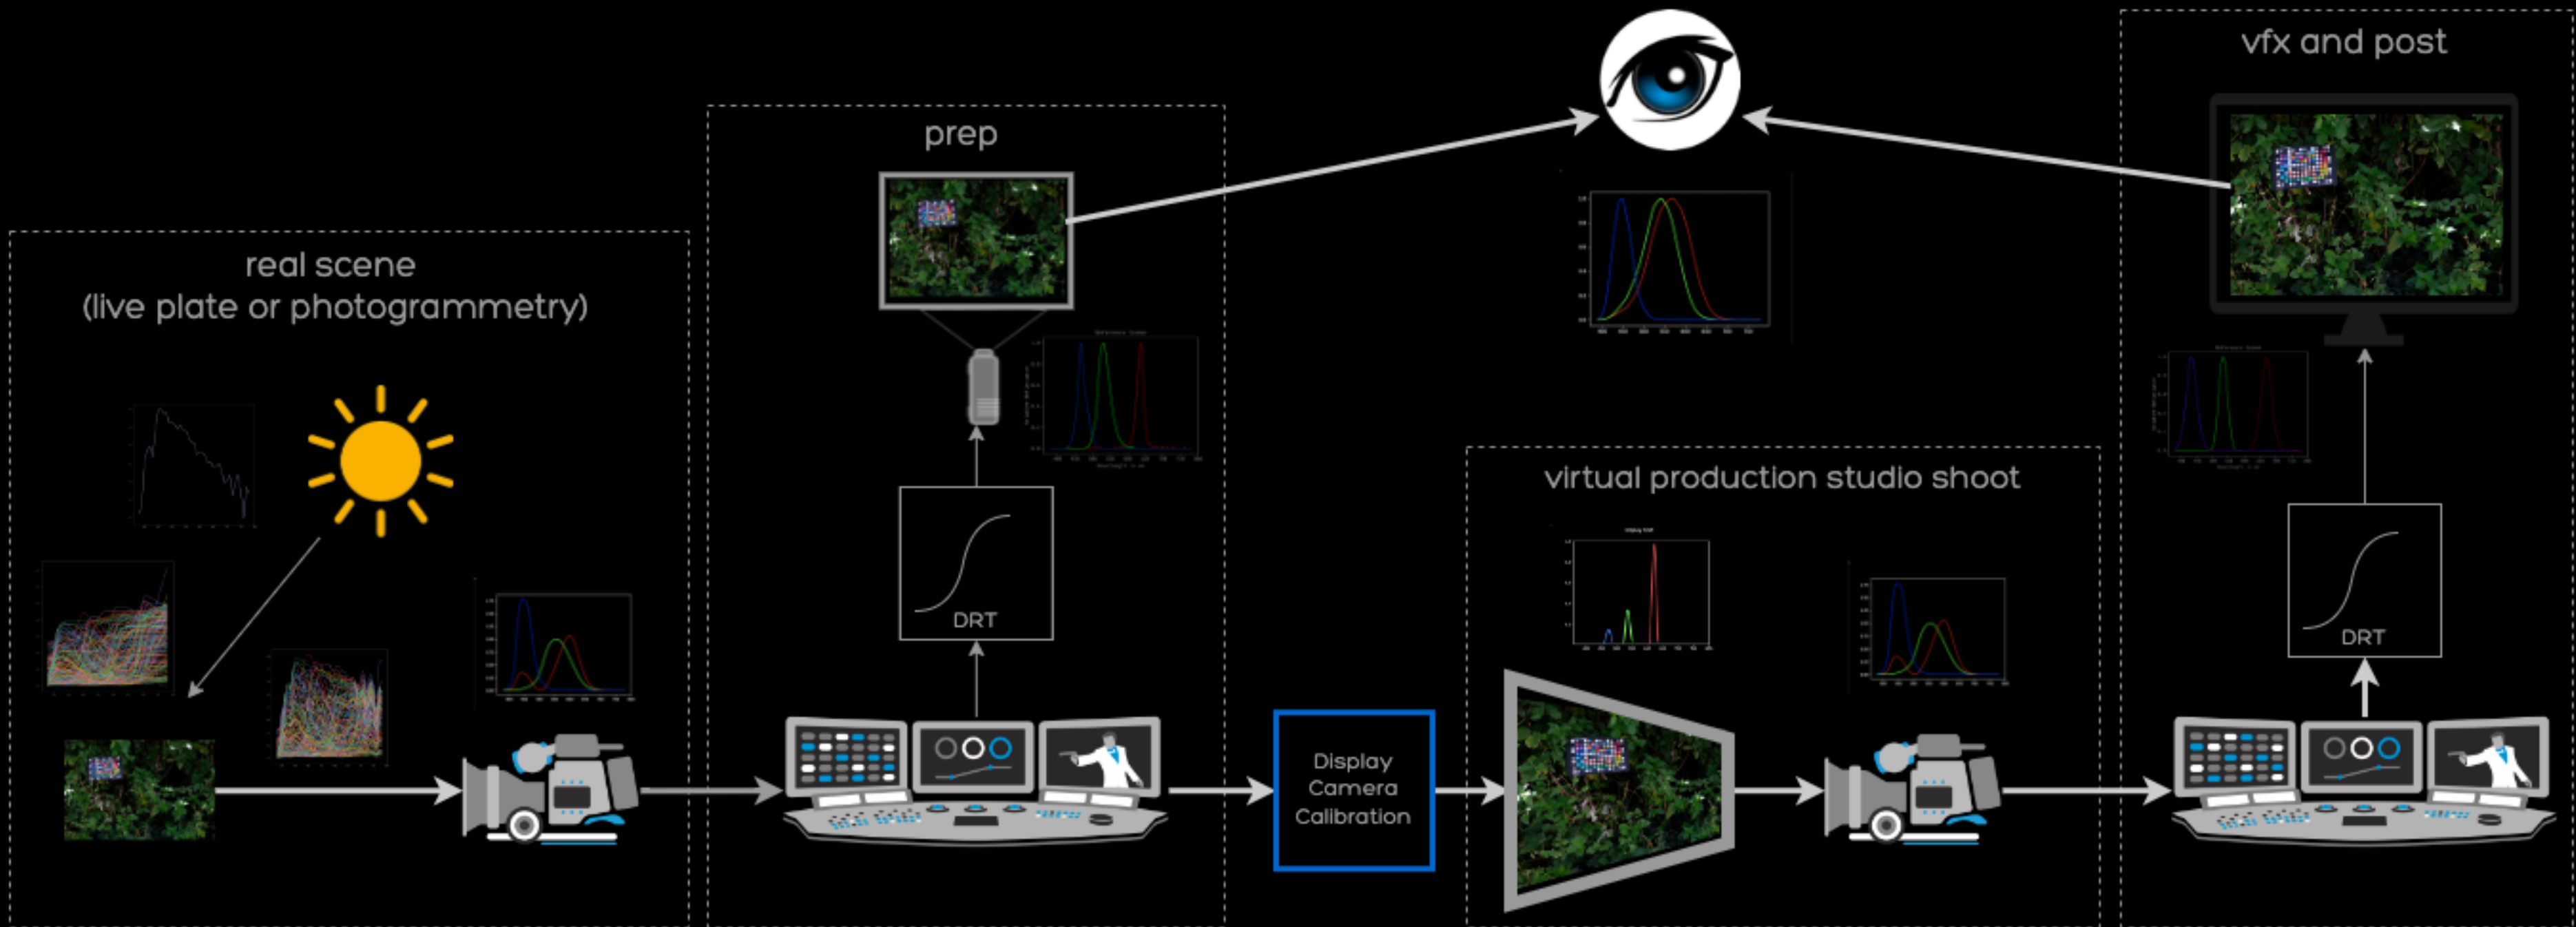

Calibration

Calibration

Avoid those Pitfalls:

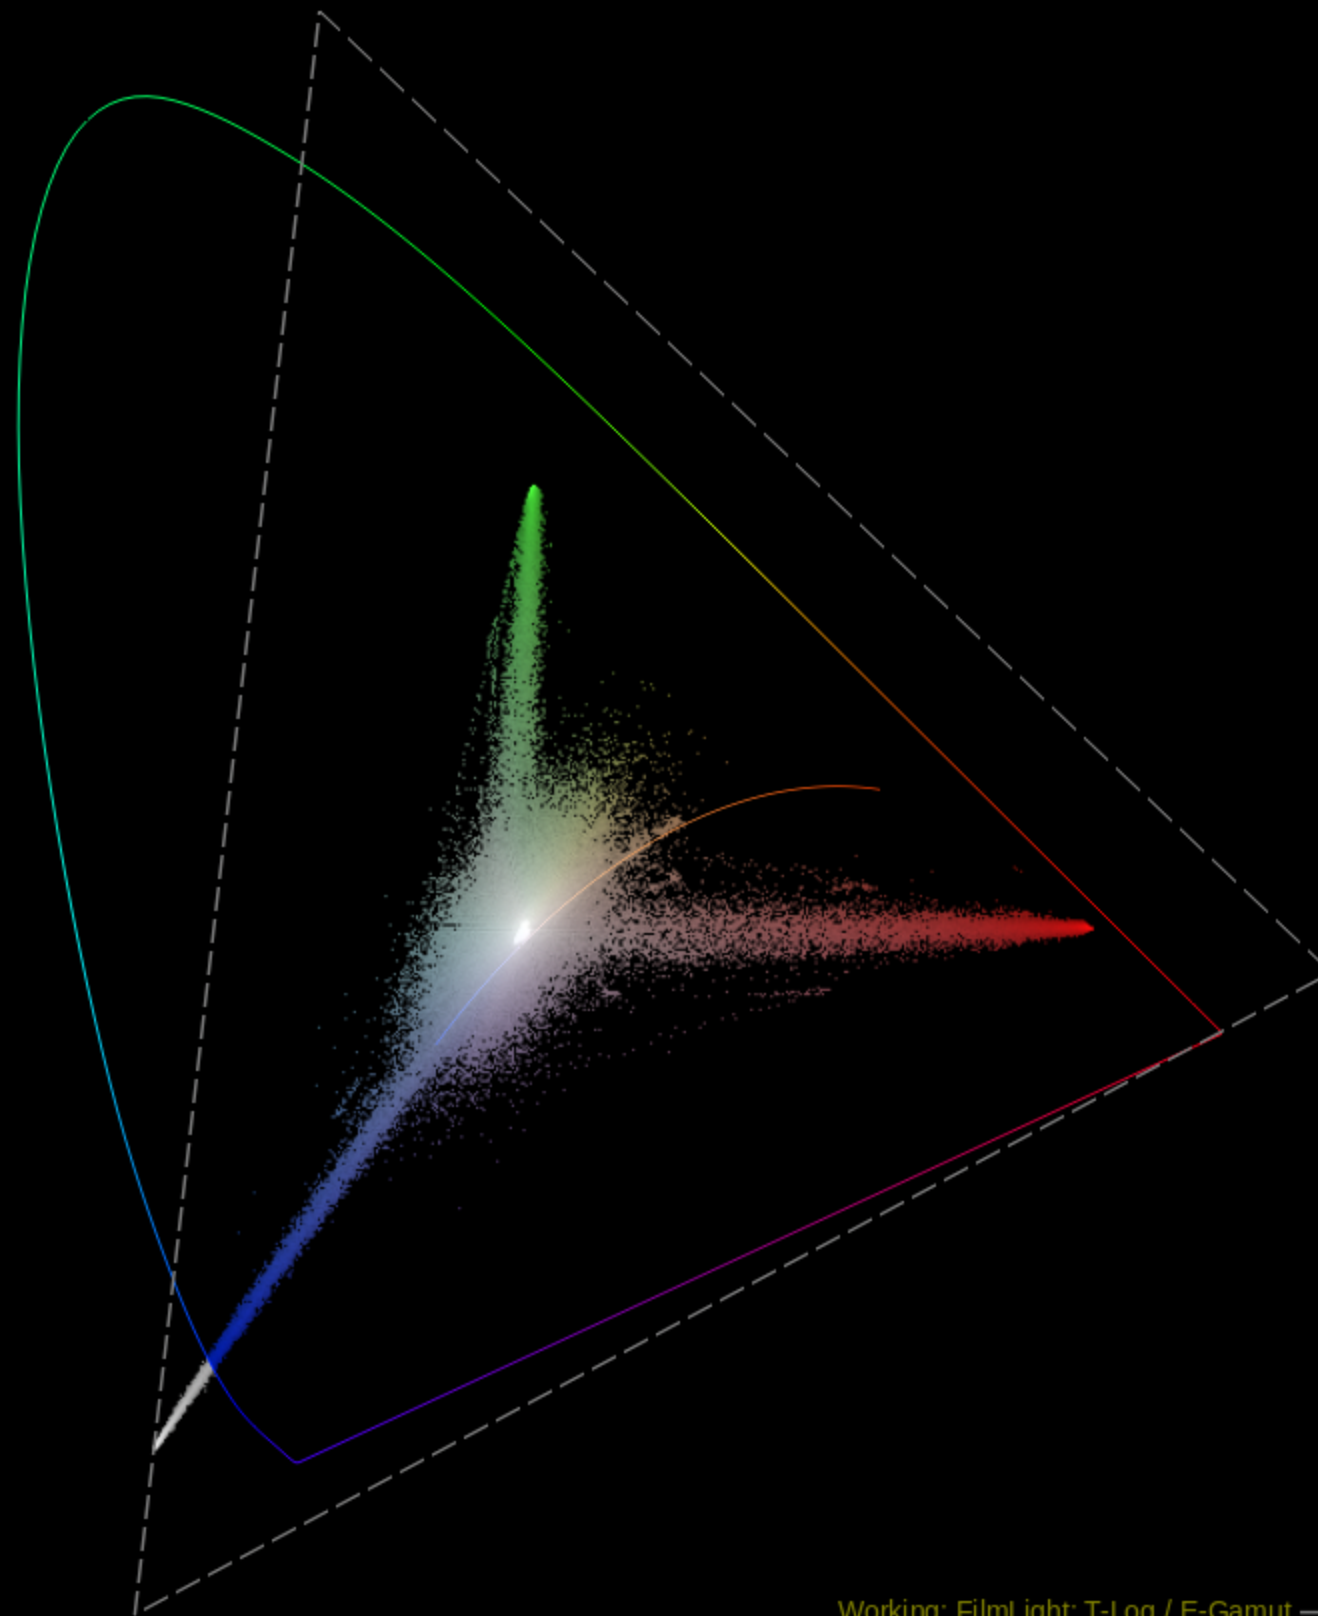

1. driving the virtual production display in a preset like P3 or Rec.2020
2. calibrate the colours with a spectrometer or colourimeter
3. sending display referred media to the virtual production wall

Instead:

- driving the virtual production display in the native gamut
- calibrating the virtual production display with the production camera
- stream scene-referred image state to the virtual production display

Native gamut

as seen by the virtual production camera

Native gamut

reproduction

original

No Metamers

$$C_{bg} \neq C_{fg}$$

Fix the lighting

$$C_{fg} = \textit{Object} * \textit{Light}$$

change lights until

$$C_{bg} = C_{fg}$$

*overall minimisation
full-colour match is impractical*

Grading to solve the equation

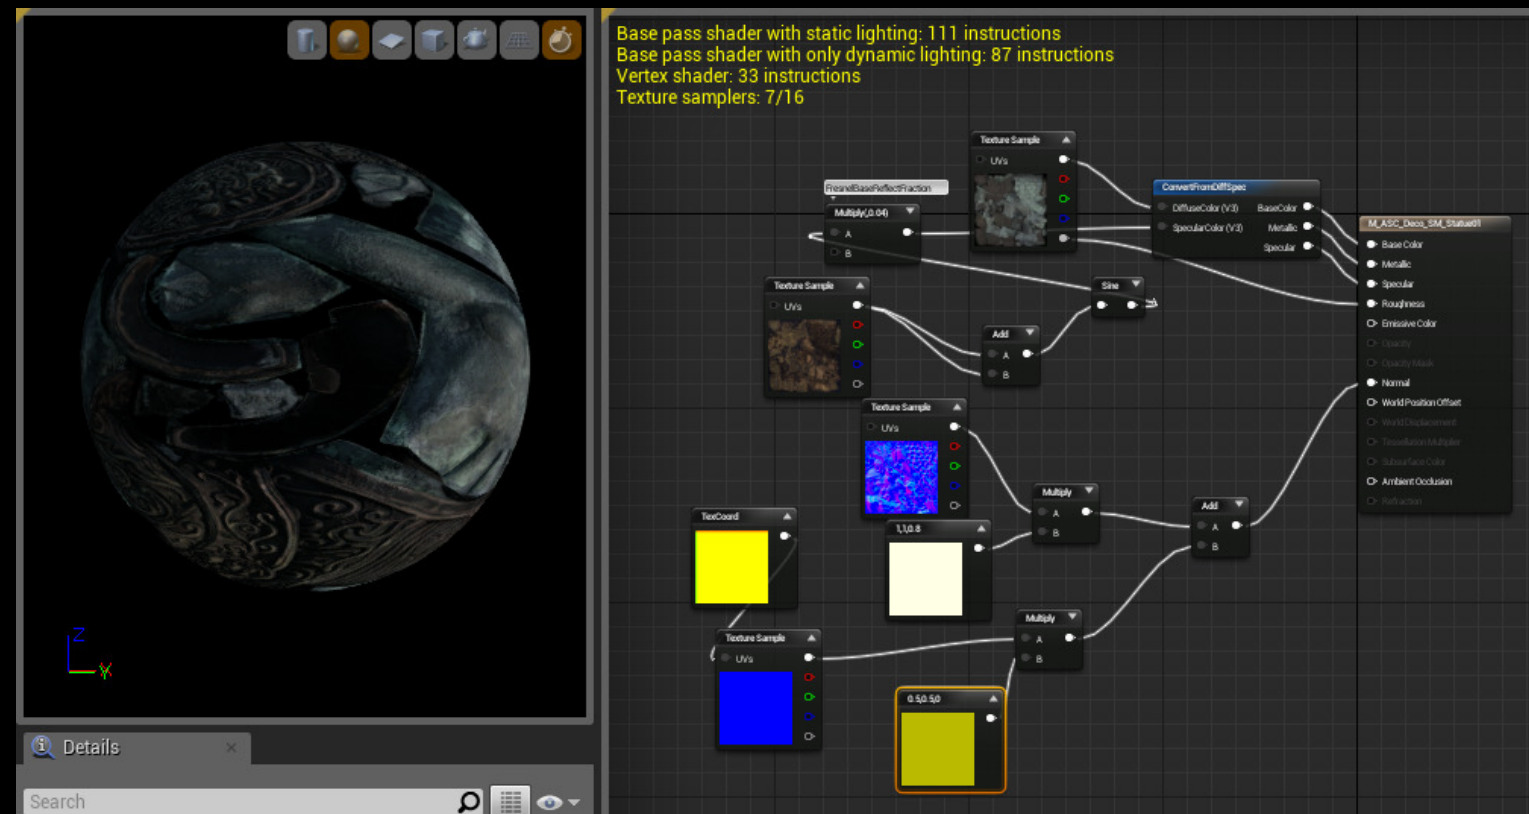

$$f_{grading}(C_{bg}) = C_{fg}$$

Not so fast!

Modify the RT Engine Scene directly until

$$C_{bg} = C_{fg}$$

In theory, the best solution

- works only for objects rendered in RT
- Shader controls can be complex
- RT Engine native controls can lack intuition
- Object colours might be modified by post-process
- slow if you need to modify many objects

Grading to solve the equation

$$f_{grading}(C_{bg}) = C_{fg}$$

includes

$$f_{grading}\left(\sum_i^n f_{grading}(C_{bg_i})\right) = \sum_i^n C_{fg_i}$$

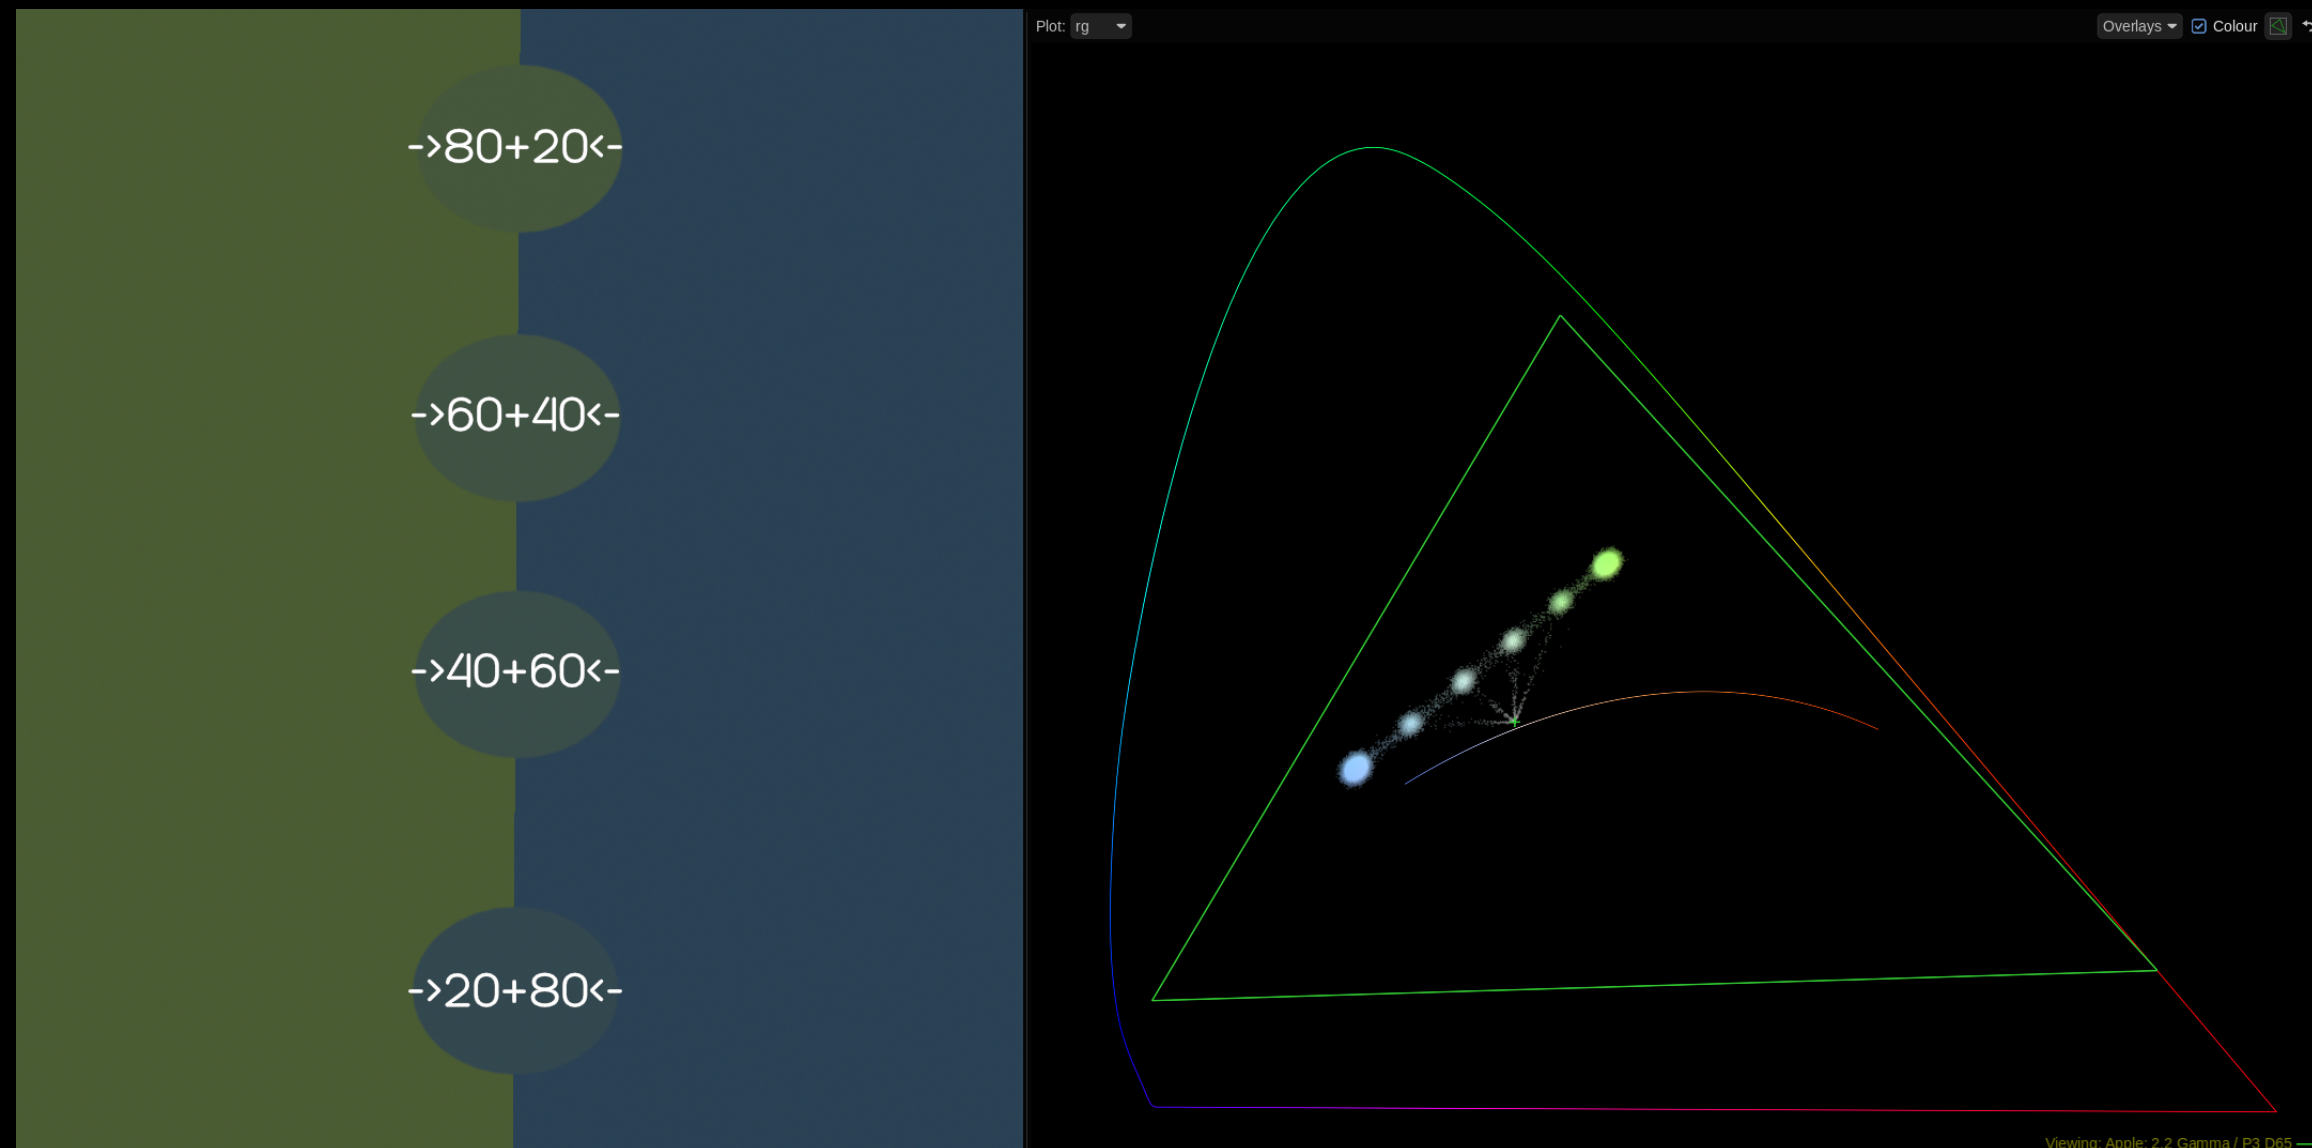

Requiriements:

- scene-referred pipeline
- physically plausible (additive colour mixture)
- fast and constant to execute
- applicable both on objects and output
- linear light processing
- easy to use
 - predictable
 - fast learning curve
 - operated by none colour experts

Additive Colour Mixture

the additive mixture of two lights produces a light which falls on a straight line connecting the two lights (in the observer space)

Some matching experiments

Conclusion

- Linear Light Gains (aka white balance) for a single colour/object/colour location
- Keys, HSV, or scale-based tools distorted the nature of the additive mixture
- perceptual tools are not helpful (additive mixture)
- 3x3 matrix only works for three colours
- XGrade type grade looks like a promising solution

sometimes, the correct solution is not achievable
prelighting and colour-matching foreground and background can be
speeded up dramatically
